CERN experiment brings precision to a cornerstone of particle physics

11 Feb 2015

Geneva, 11 February 2015. In a paper published yesterday in the journal *Physical Review Letters*, the COMPASS experiment at CERN¹ reports a key measurement on the strong interaction. The strong interaction binds quarks into protons and neutrons, and protons and neutrons into the nuclei of all the elements from which matter is built. Inside those nuclei, particles called pions made up of a quark and an antiquark mediate the interaction. Strong interaction theory makes a precise prediction on the polarisability of pions – the degree to which their shape can be stretched. This polarisability has baffled scientists since the 1980s, when the first measurements appeared to be at odds with the theory. Today's result is in close agreement with theory.

“The theory of the strong interaction is one of the cornerstones of our understanding of nature at the level of the fundamental particles,” said Fabienne Kunne and Andrea Bressan, spokespersons of the COMPASS experiment, *“so this result, in perfect agreement with the theory, is a very important one.”*

Polarizabilities of a medium

Polarizabilities

$$\vec{P} = \underline{\alpha} \vec{E}$$
$$\vec{\mu} = \underline{\beta} \vec{H}$$

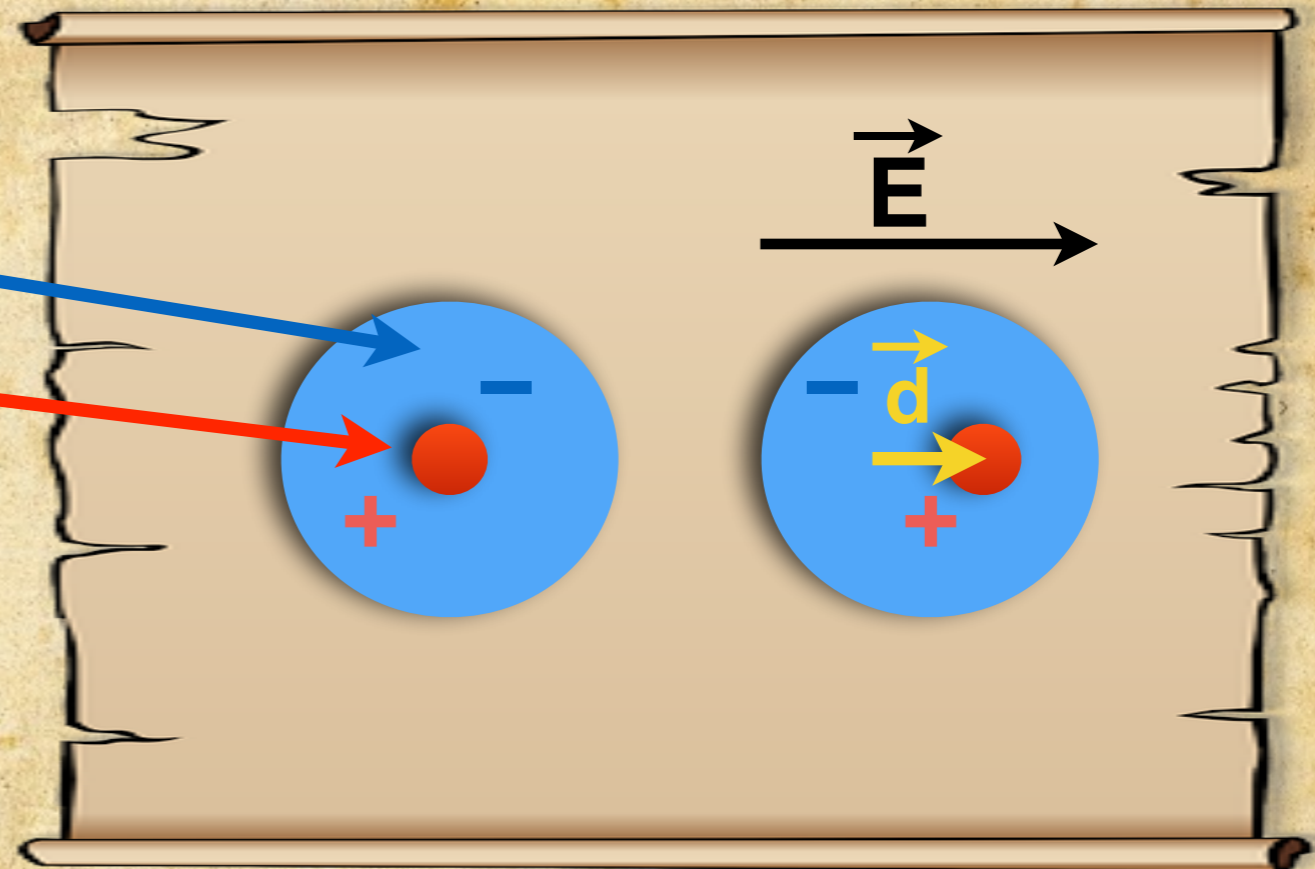

Hydrogen atom

- the simplest QED system

electron shell

proton

$$\alpha_{\text{H}} = \frac{9}{2} a^3, \text{ where } a \text{ is the Bohr radius}$$

Polarizabilities of hadrons

Compton amplitude:

$$A(\gamma X \rightarrow \gamma X) =$$

$$\left(-\frac{\alpha}{m} \delta_{o\pm} + \alpha_X \omega_1 \omega_2\right) \hat{e}_1 \cdot \hat{e}_2 +$$

$$+ \beta_X \omega_1 \omega_2 (\hat{e}_1 \times \hat{q}_1) (\hat{e}_2 \times \hat{q}_2) + \dots$$

The electric and magnetic polarizabilities of a hadron are the quantities characterizing the rigidity of QCD system

$$H = \dots - (\alpha_X E^2 + \beta_X H^2) / 2$$

$$\vec{P} = \alpha_X \vec{E}$$

$$\vec{\mu} = \beta_X \vec{H}$$

PDG data:

	$\alpha_X, 10^{-4} \text{ fm}^3$	$\beta_X, 10^{-4} \text{ fm}^3$
p	12.0 ± 0.6	1.9 ∓ 0.6
n	12.5 ± 1.7	2.7 ∓ 1.8

$\pi, K?$

Mass: Higgs boson vs. QCD

2.3 MeV

2.3 MeV

4.8 MeV

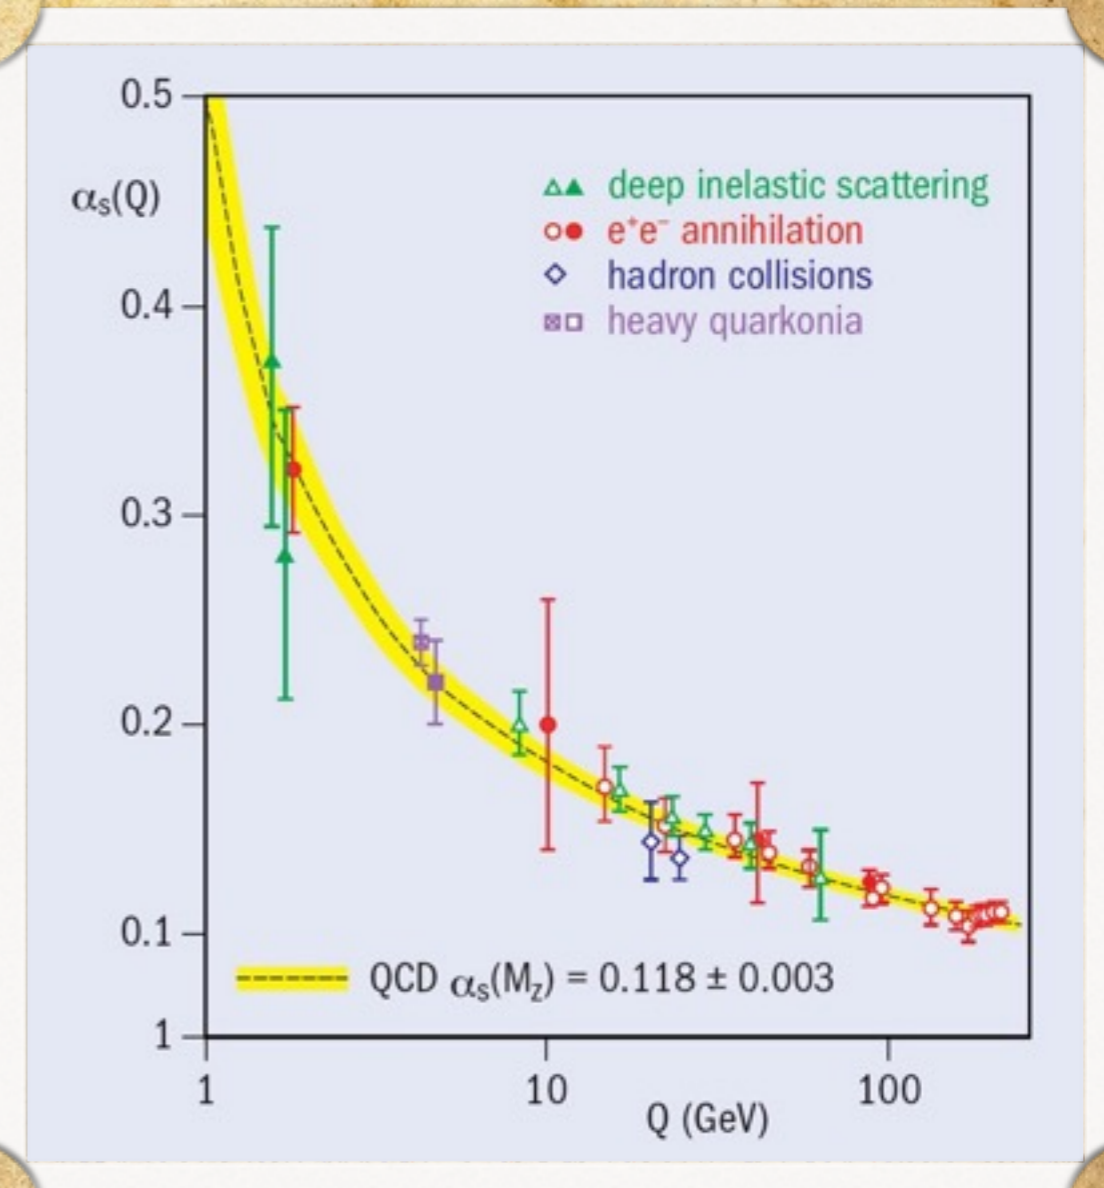

= 938 MeV

?

QCD - true theory of strong interactions, but...

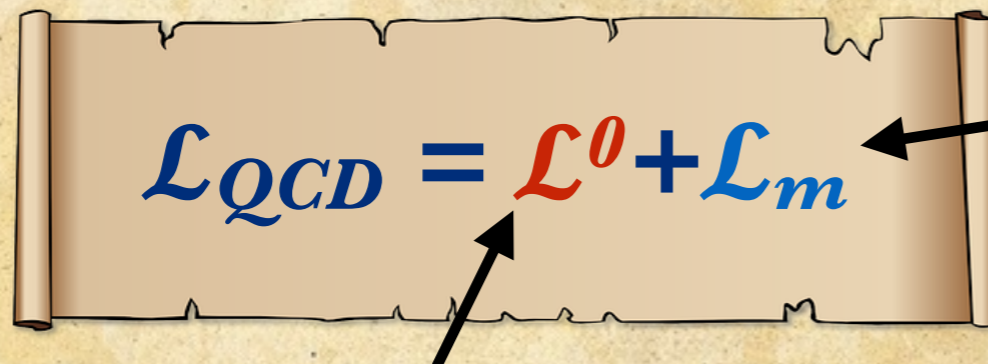

Since the constant of strong interactions $\alpha_s \sim 1$ at small energies, exact QCD formalism cannot make predictions with reasonable accuracy.

Effective phenomenological models are needed

Chiral perturbation theory

Mass of light quarks (m, d) is much smaller than the typical scale $M \approx 1 \text{ GeV}$

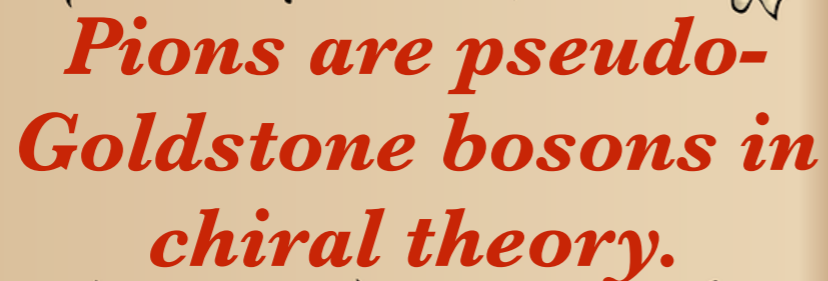

$$\mathcal{L}_{\text{QCD}} = \mathcal{L}^0 + \mathcal{L}_m$$

mass term -
a small perturbation

Chiral symmetric term

m_q/M , p/M - small parameters in expansion

Approximate chiral symmetry is in lagrangian but not in the mass spectrum of hadrons!

Pions are pseudo-Goldstone bosons in chiral theory.

Pion polarizabilities: prediction

<i>Model</i>	<i>Parameter</i>	10^{-4} fm^3
<i>χPT (1-loop)</i>	$a_{\pi}-\beta_{\pi}$	5.4 ± 0.8
	$a_{\pi}+\beta_{\pi}$	0
<i>χPT (2-loops)</i>	$a_{\pi}-\beta_{\pi}$	5.7 ± 1.0
	$a_{\pi}+\beta_{\pi}$	0.16
<i>Nambu-Nona-Lasinio model</i>	$a_{\pi}-\beta_{\pi}$	9.8
<i>Quark confinement model</i>	$a_{\pi}-\beta_{\pi}$	7.05
	$a_{\pi}+\beta_{\pi}$	0.23
<i>QCD sum rules</i>	$a_{\pi}-\beta_{\pi}$	11.2 ± 1.0
<i>Dispersion sum rules</i>	$a_{\pi}-\beta_{\pi}$	13.6 ± 2.15
	$a_{\pi}+\beta_{\pi}$	0.166 ± 0.024

The most of theoretical models are in agreement that $a_{\pi}-\beta_{\pi} \gg a_{\pi}+\beta_{\pi} \approx 0.2 \times 10^{-4} \text{ fm}^3$. As for value $a_{\pi}-\beta_{\pi}$, predictions are quite different

Experimental results for α_π, β_π

Data	Reaction	Parameter	$[10^{-4} fm^3]$
Serpukhov ($\alpha_\pi + \beta_\pi = 0$)	$\pi Z \rightarrow \pi Z \gamma$	α_π	$6.8 \pm 1.4 \pm 1.2$
Serpukhov ($\alpha_\pi + \beta_\pi \neq 0$)		$\alpha_\pi + \beta_\pi$	$1.4 \pm 3.1 \pm 2.8$
		β_π	$-7.1 \pm 2.8 \pm 1.8$
Lebedev	$\gamma N \rightarrow \gamma N \pi$	α_π	20 ± 12
Mami A2	$\gamma p \rightarrow \gamma \pi^+ n$	$\alpha_\pi - \beta_\pi$	$11.6 \pm 1.5 \pm 3.0 \pm 0.5$
PLUTO	$\gamma\gamma \rightarrow \pi^+ \pi^-$	α_π	$19.1 \pm 4.8 \pm 5.7$
DM1	$\gamma\gamma \rightarrow \pi^+ \pi^-$	α_π	17.2 ± 4.6
DM2	$\gamma\gamma \rightarrow \pi^+ \pi^-$	α_π	26.3 ± 7.4
Mark II	$\gamma\gamma \rightarrow \pi^+ \pi^-$	α_π	2.2 ± 1.6
Combined fit: MARK II, VENUS, ALEPH, TPC/2 γ , CELLO, BELLE (L. Fil'kov, V. Kashevarov)	$\gamma\gamma \rightarrow \pi^+ \pi^-$	$\alpha_\pi - \beta_\pi$	$13.0^{+2.6}_{-1.9}$
		$\alpha_\pi + \beta_\pi$	$0.18^{+0.11}_{-0.02}$
Combined fit: MARK II, Crystal Ball (A. Kaloshin, V. Serebryakov)	$\gamma\gamma \rightarrow \pi^+ \pi^-$	$\alpha_\pi - \beta_\pi$	5.25 ± 0.95

At the moment experimental uncertainty for pion polarizabilities is too high. New experiments are needed!

Primakoff reactions

Henry Primakoff

Photo-Production of Neutral Mesons in Nuclear Electric Fields and the Mean Life of the Neutral Meson*

H. PRIMAKOFF†

Laboratory for Nuclear Science and Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts

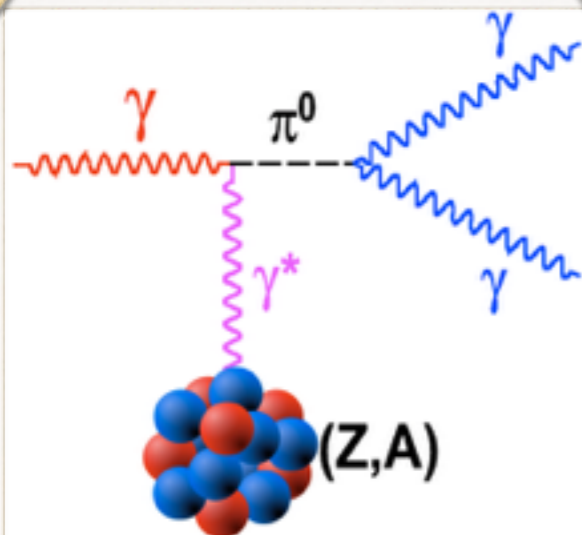

January 2, 1951

IT has now been well established experimentally that neutral π -mesons (π^0) decay into two photons.¹ Theoretically, this two-photon type of decay implies zero π^0 spin;² in addition, the decay has been interpreted as proceeding through the mechanism of the creation and subsequent radiative recombination of a virtual proton anti-proton pair.³ Whatever the actual mechanism of the (two-photon) decay, its mere existence implies an effective interaction between the π^0 wave field, φ , and the electromagnetic wave field, \mathbf{E}, \mathbf{H} , representable in the form:

$$\text{Interaction Energy Density} = \eta(\hbar/\mu c)(\hbar c)^{-\frac{1}{2}} \varphi \mathbf{E} \cdot \mathbf{H}. \quad (1)$$

Here φ has been assumed pseudoscalar, the factors $\hbar/\mu c$ and $(\hbar c)^{-\frac{1}{2}}$ are introduced for dimensional reasons ($\mu \equiv$ rest mass of π^0),

Coulomb field of a nucleus can be used as photon target

From Primakoff effect to Primakoff reactions

Equivalent photons approach

(Weizsaecker-Williams approximation)

Electromagnetic field of fast charged particle is similar to a field of flat electromagnetic wave

$$\sigma_{xy}(\omega, Q^2) \rightarrow \sigma_{xy}(\omega, 0)$$

$$d\sigma_{xz} = \int n_\gamma(\omega) d\sigma_{xy}(\omega) d\omega$$

density of equivalent photons

Pion polarizabilities and Primakoff cross section

$$\frac{d\sigma}{ds dt dQ^2} = \frac{Z^2 \alpha}{\pi(s - m_\pi^2)} \cdot F_{\text{eff}}^2(Q^2) \cdot \frac{Q^2 - Q_{\text{min}}^2}{Q^4} \cdot \frac{d\sigma_{\pi\gamma}}{dt}$$

$$Q_{\text{min}} = (s - m_\pi^2)/2E_{\text{beam}}$$

Compton cross section:

$$\frac{d\sigma_{\pi\gamma}}{d\Omega_{\text{cm}}} = \frac{\alpha^2(s^2 z_+^2 + m_\pi^4 z_-^2)}{s(sz_+ + m_\pi^2 z_-)^2} - \frac{\alpha m_\pi^3 (s - m_\pi^2)^2}{4s^2(sz_+ + m_\pi^2 z_-)} \cdot \mathcal{P}$$

$$z_\pm = 1 \pm \cos \theta_{\text{cm}}$$

$$\mathcal{P} = z_-^2(\alpha_\pi - \beta_\pi) + \frac{s^2}{m_\pi^4} z_+^2(\alpha_\pi + \beta_\pi)$$

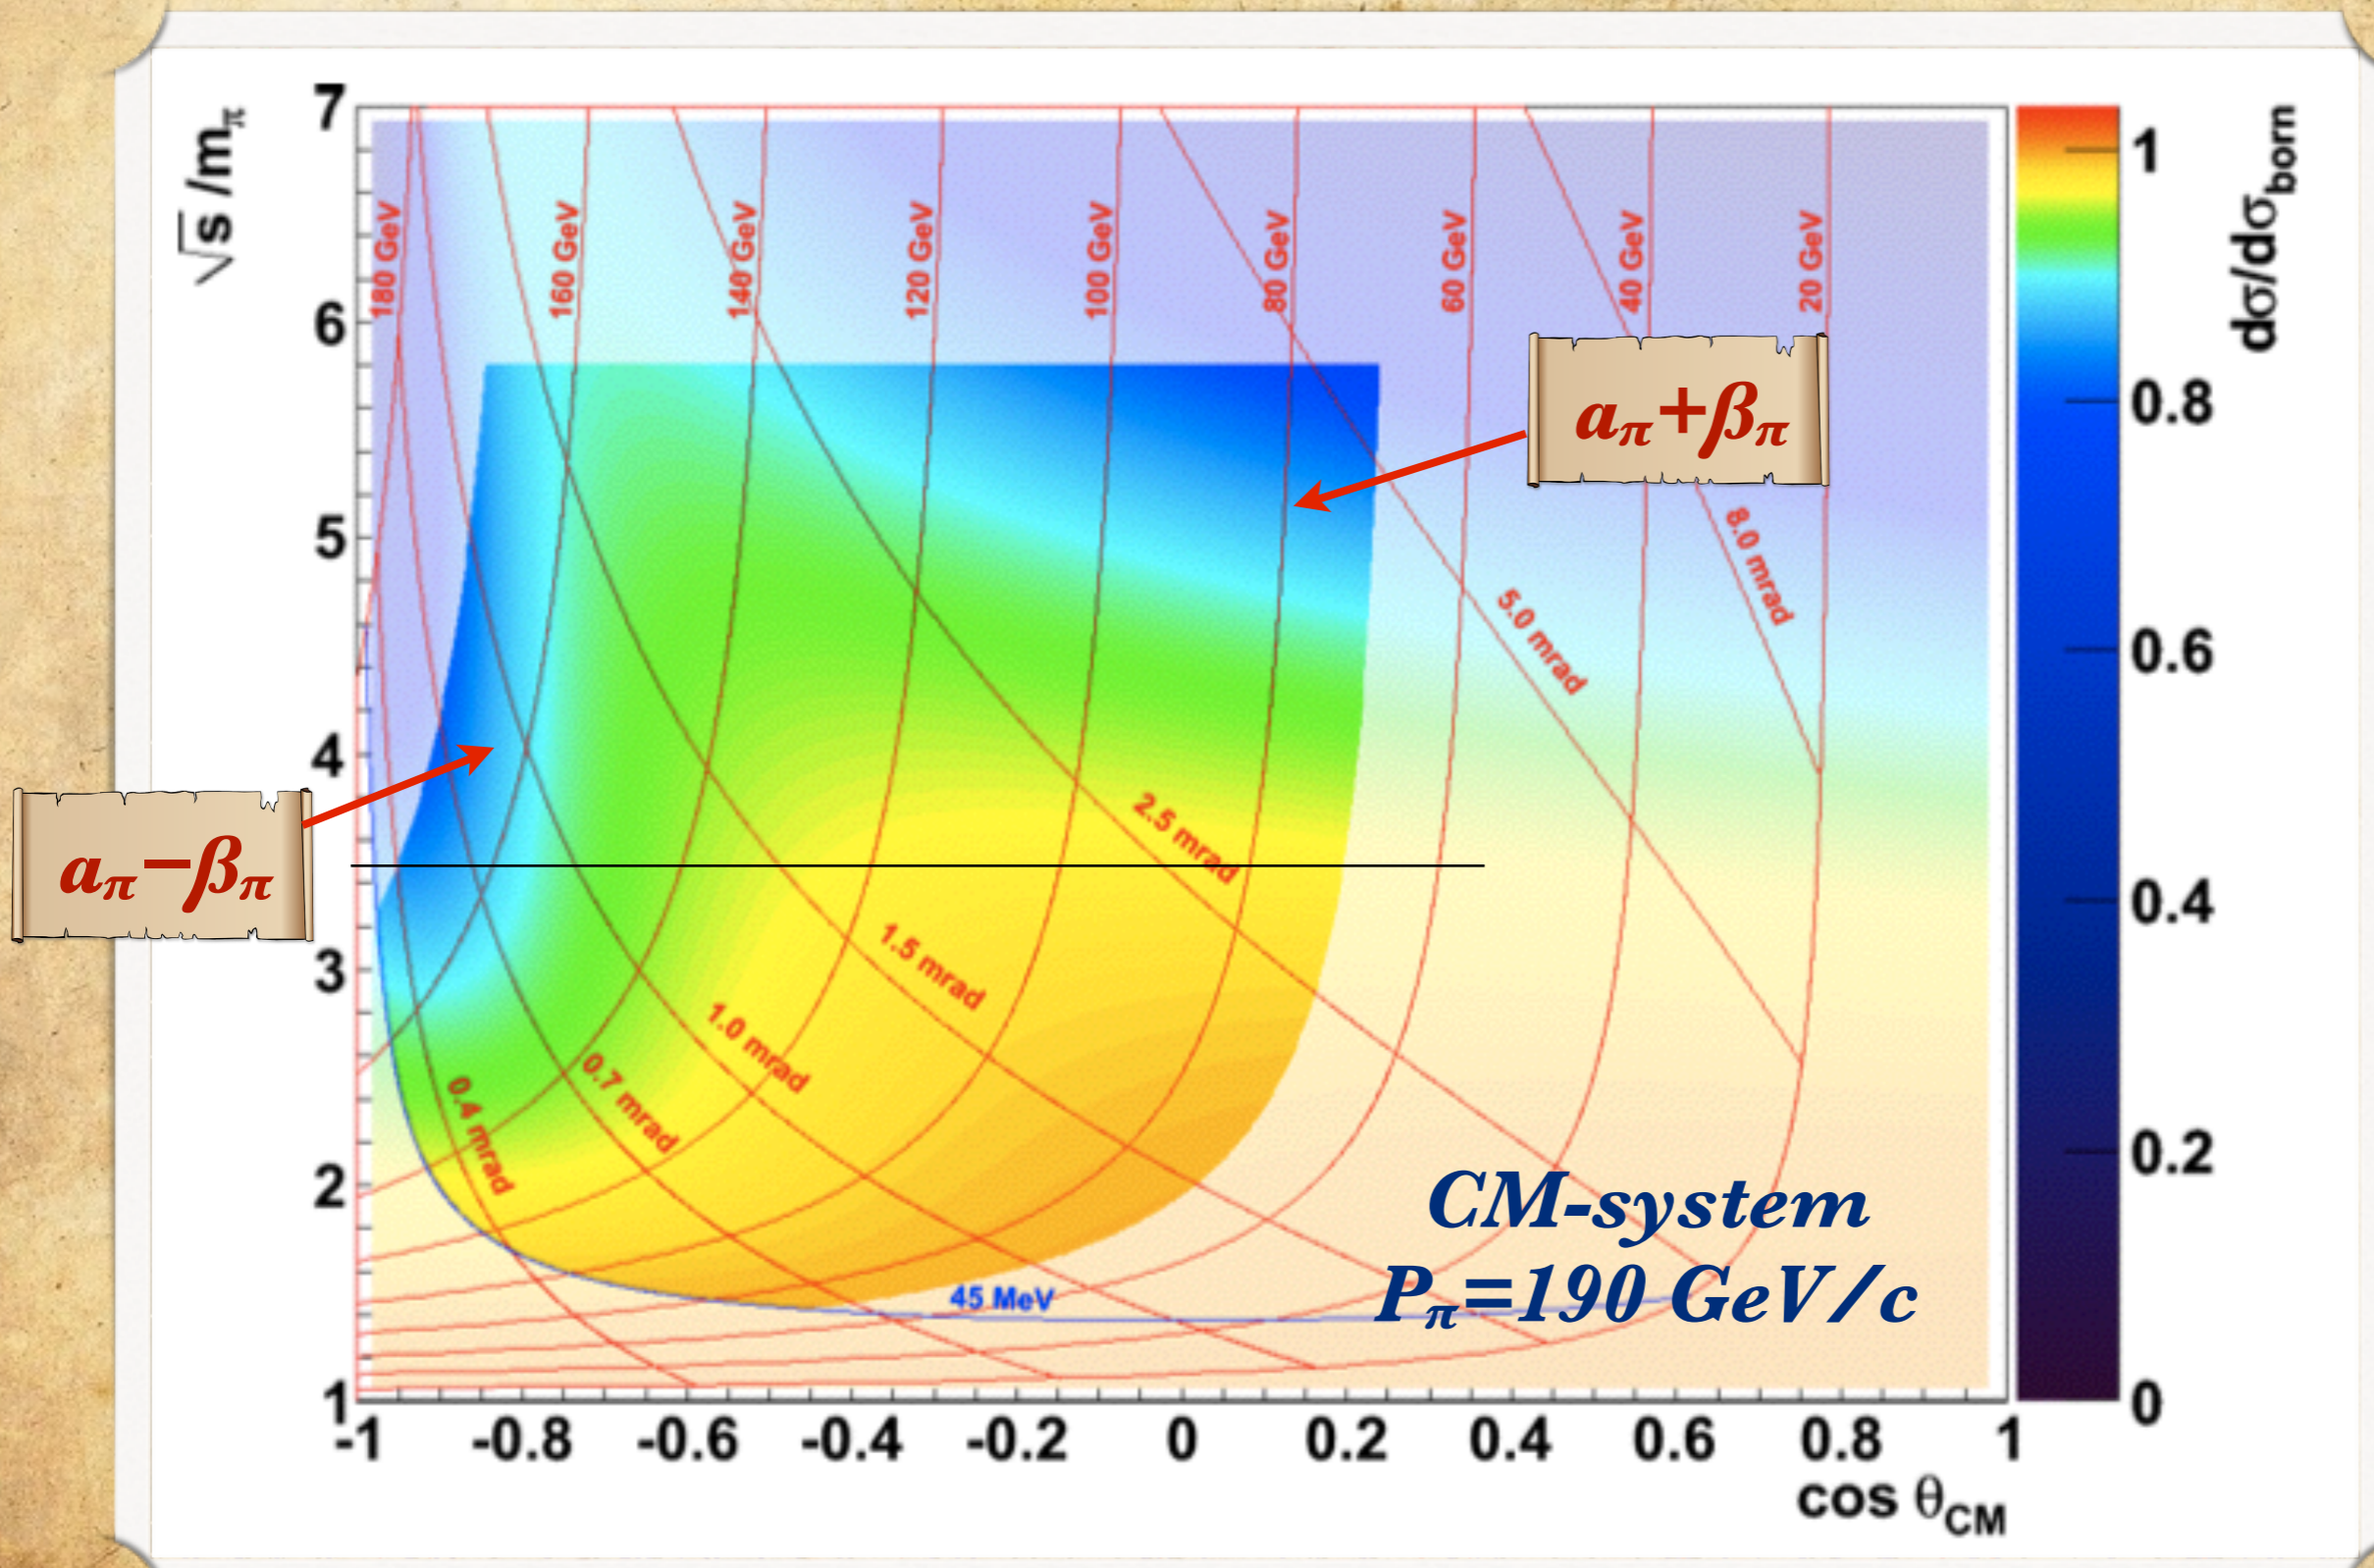

$$Q^2 \ll m_\pi^2$$

$$\sigma \sim Z^2$$

α_π and β_π can be extracted separately from the measurement of the differential cross section

Polarizability effects

Simple case: $a_\pi = -\beta_\pi$

$$R = \frac{\sigma}{\sigma_{p.l.}} \approx 1 - \frac{3}{2} \cdot \frac{x_\gamma^2}{1 - x_\gamma} \cdot \frac{m_\pi^3}{\alpha} \cdot a_\pi$$

x_γ - relative energy of emitted photon in **Lab** system

Pion polarizability and JINR

Retrospective review

$$a_\pi = -\beta_\pi = (6.8 \pm 1.4_{stat} \pm 1.2_{syst}) \times 10^{-4} \text{ fm}^3$$

$$a_\pi + \beta_\pi = (1.4 \pm 3.1_{stat} \pm 2.8_{syst}) \times 10^{-4} \text{ fm}^3$$

$$a_\pi = (7.8 \pm 2.8_{stat} \pm 1.8_{syst}) \times 10^{-4} \text{ fm}^3$$

The COMPASS experiment

COMPASS (Common Muon Proton Apparatus for Structure and Spectroscopy)

is the fixed target experiment on the secondary beam of Super Proton Synchrotron at CERN

The purpose of this experiment is the study of hadron structure and hadron spectroscopy with high intensity muon and hadron beams.

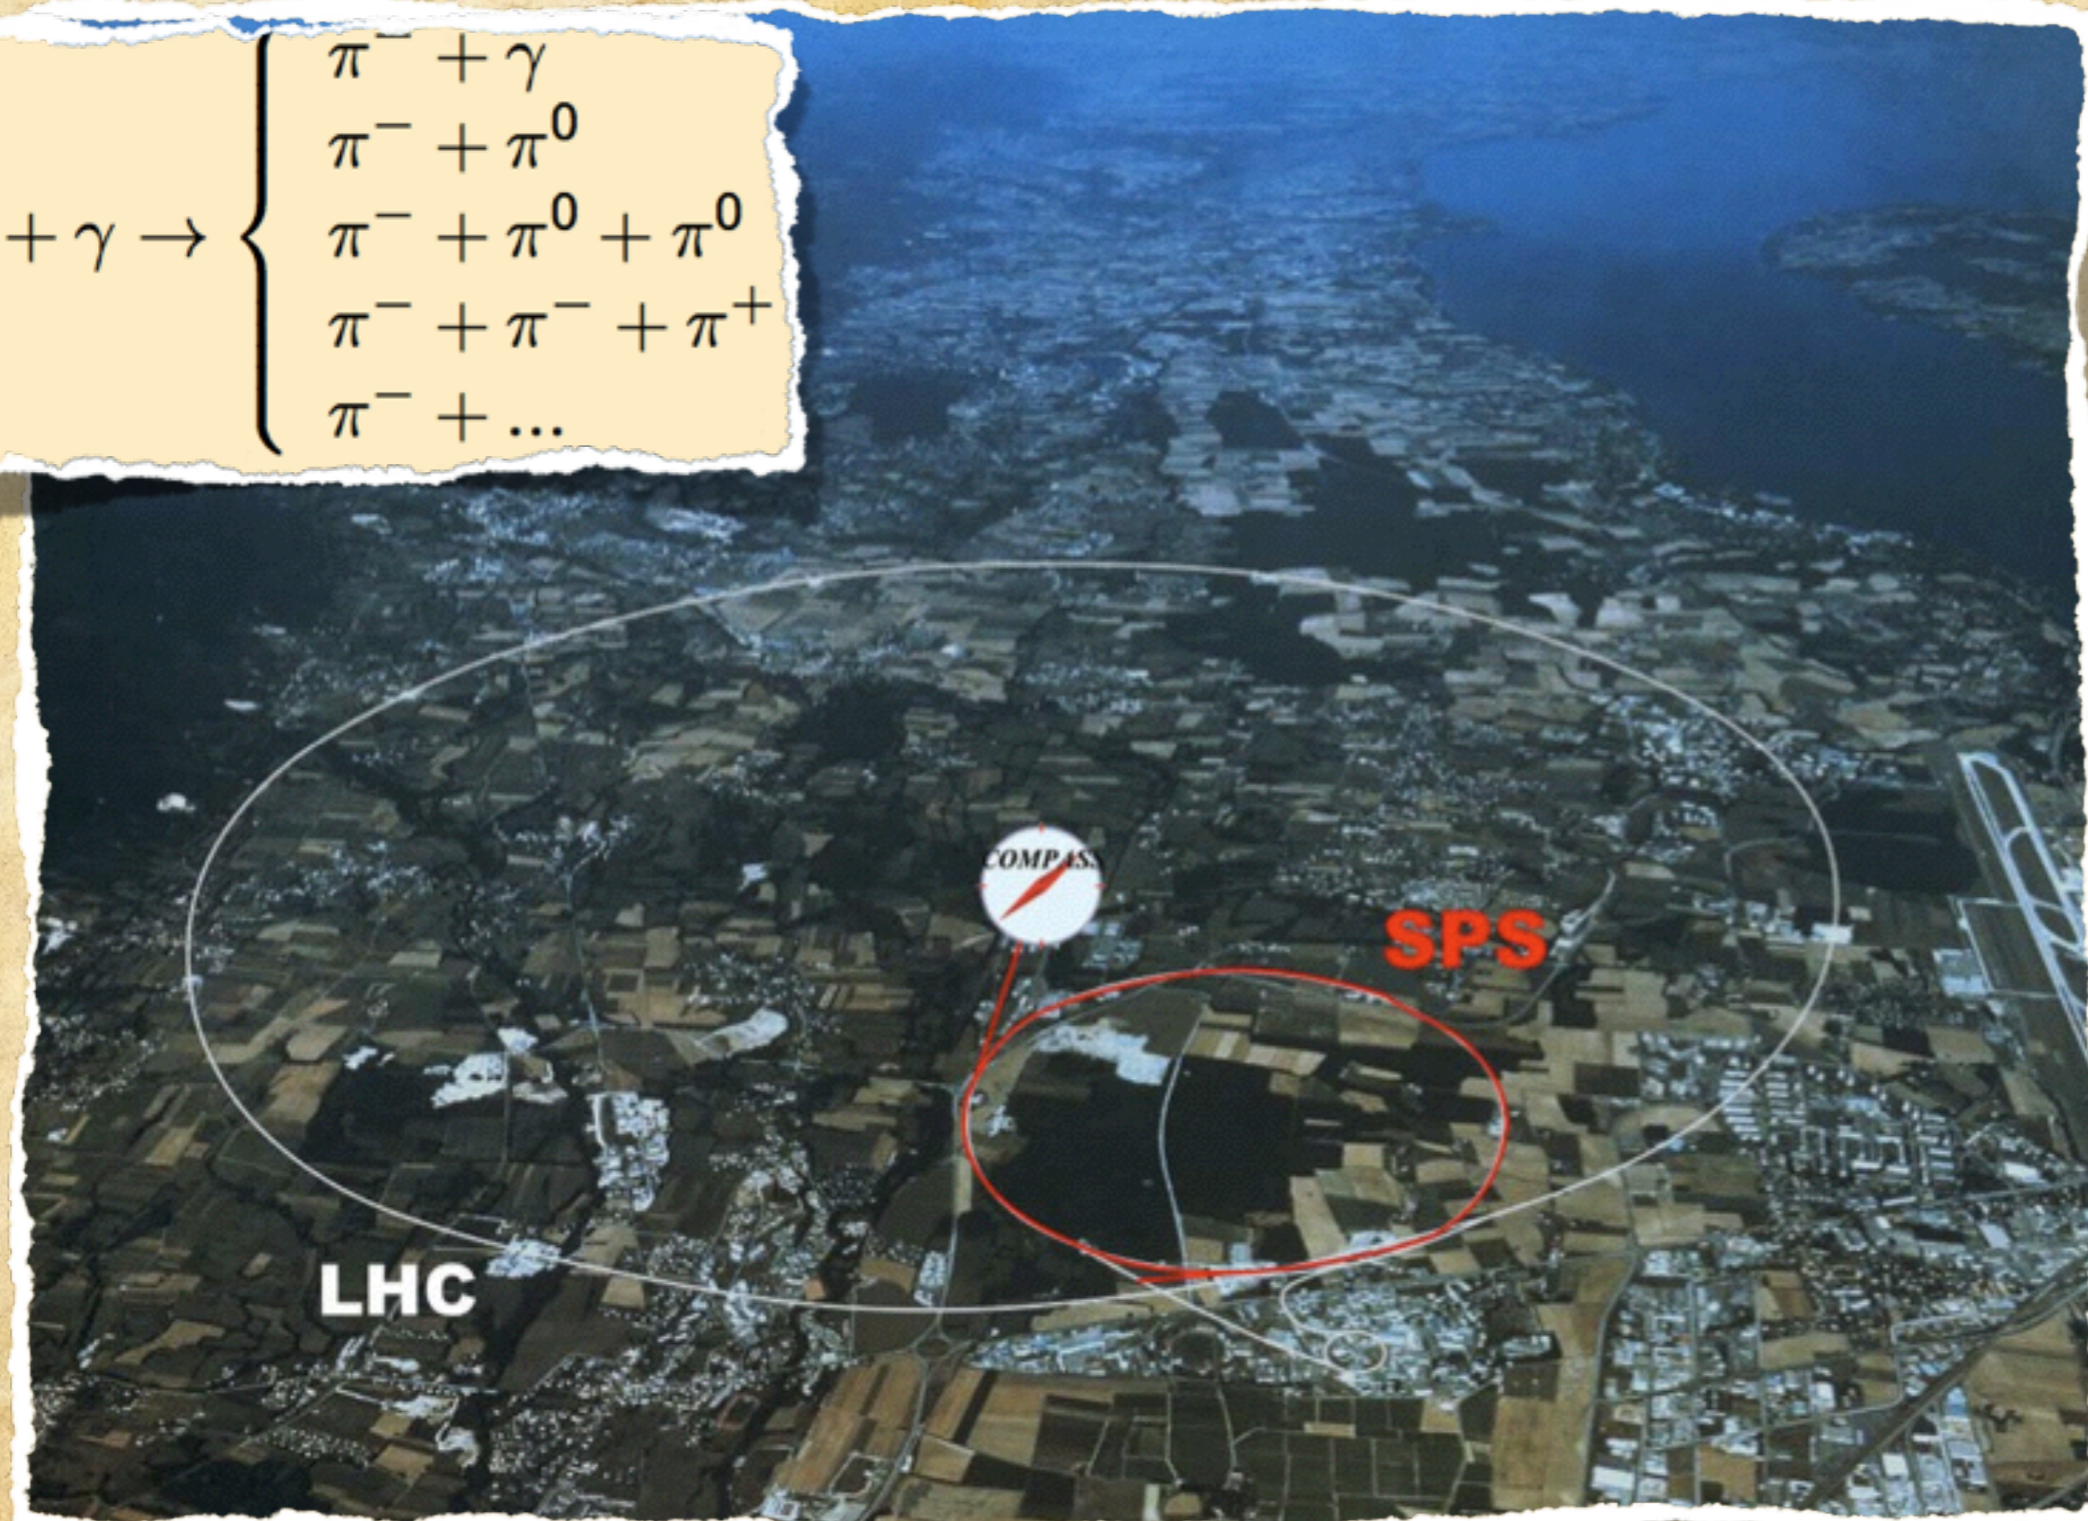

*1996 - Proposal
2002-2011 - Physical data taking*

*11 countries,
28 institutions,
~240 physicists*

COMPASS at CERN

$$\pi^- + \gamma \rightarrow \begin{cases} \pi^- + \gamma \\ \pi^- + \pi^0 \\ \pi^- + \pi^0 + \pi^0 \\ \pi^- + \pi^- + \pi^+ \\ \pi^- + \dots \end{cases}$$

The COMPASS setup

- CEDAR detectors for beam particle identification
- Precise silicon detectors to measure small scattering angles
- Magnetic spectrometer for pion momentum measurement
- Electromagnetic calorimeter with good energy and spacial resolution for photon detection
- Muon identification system

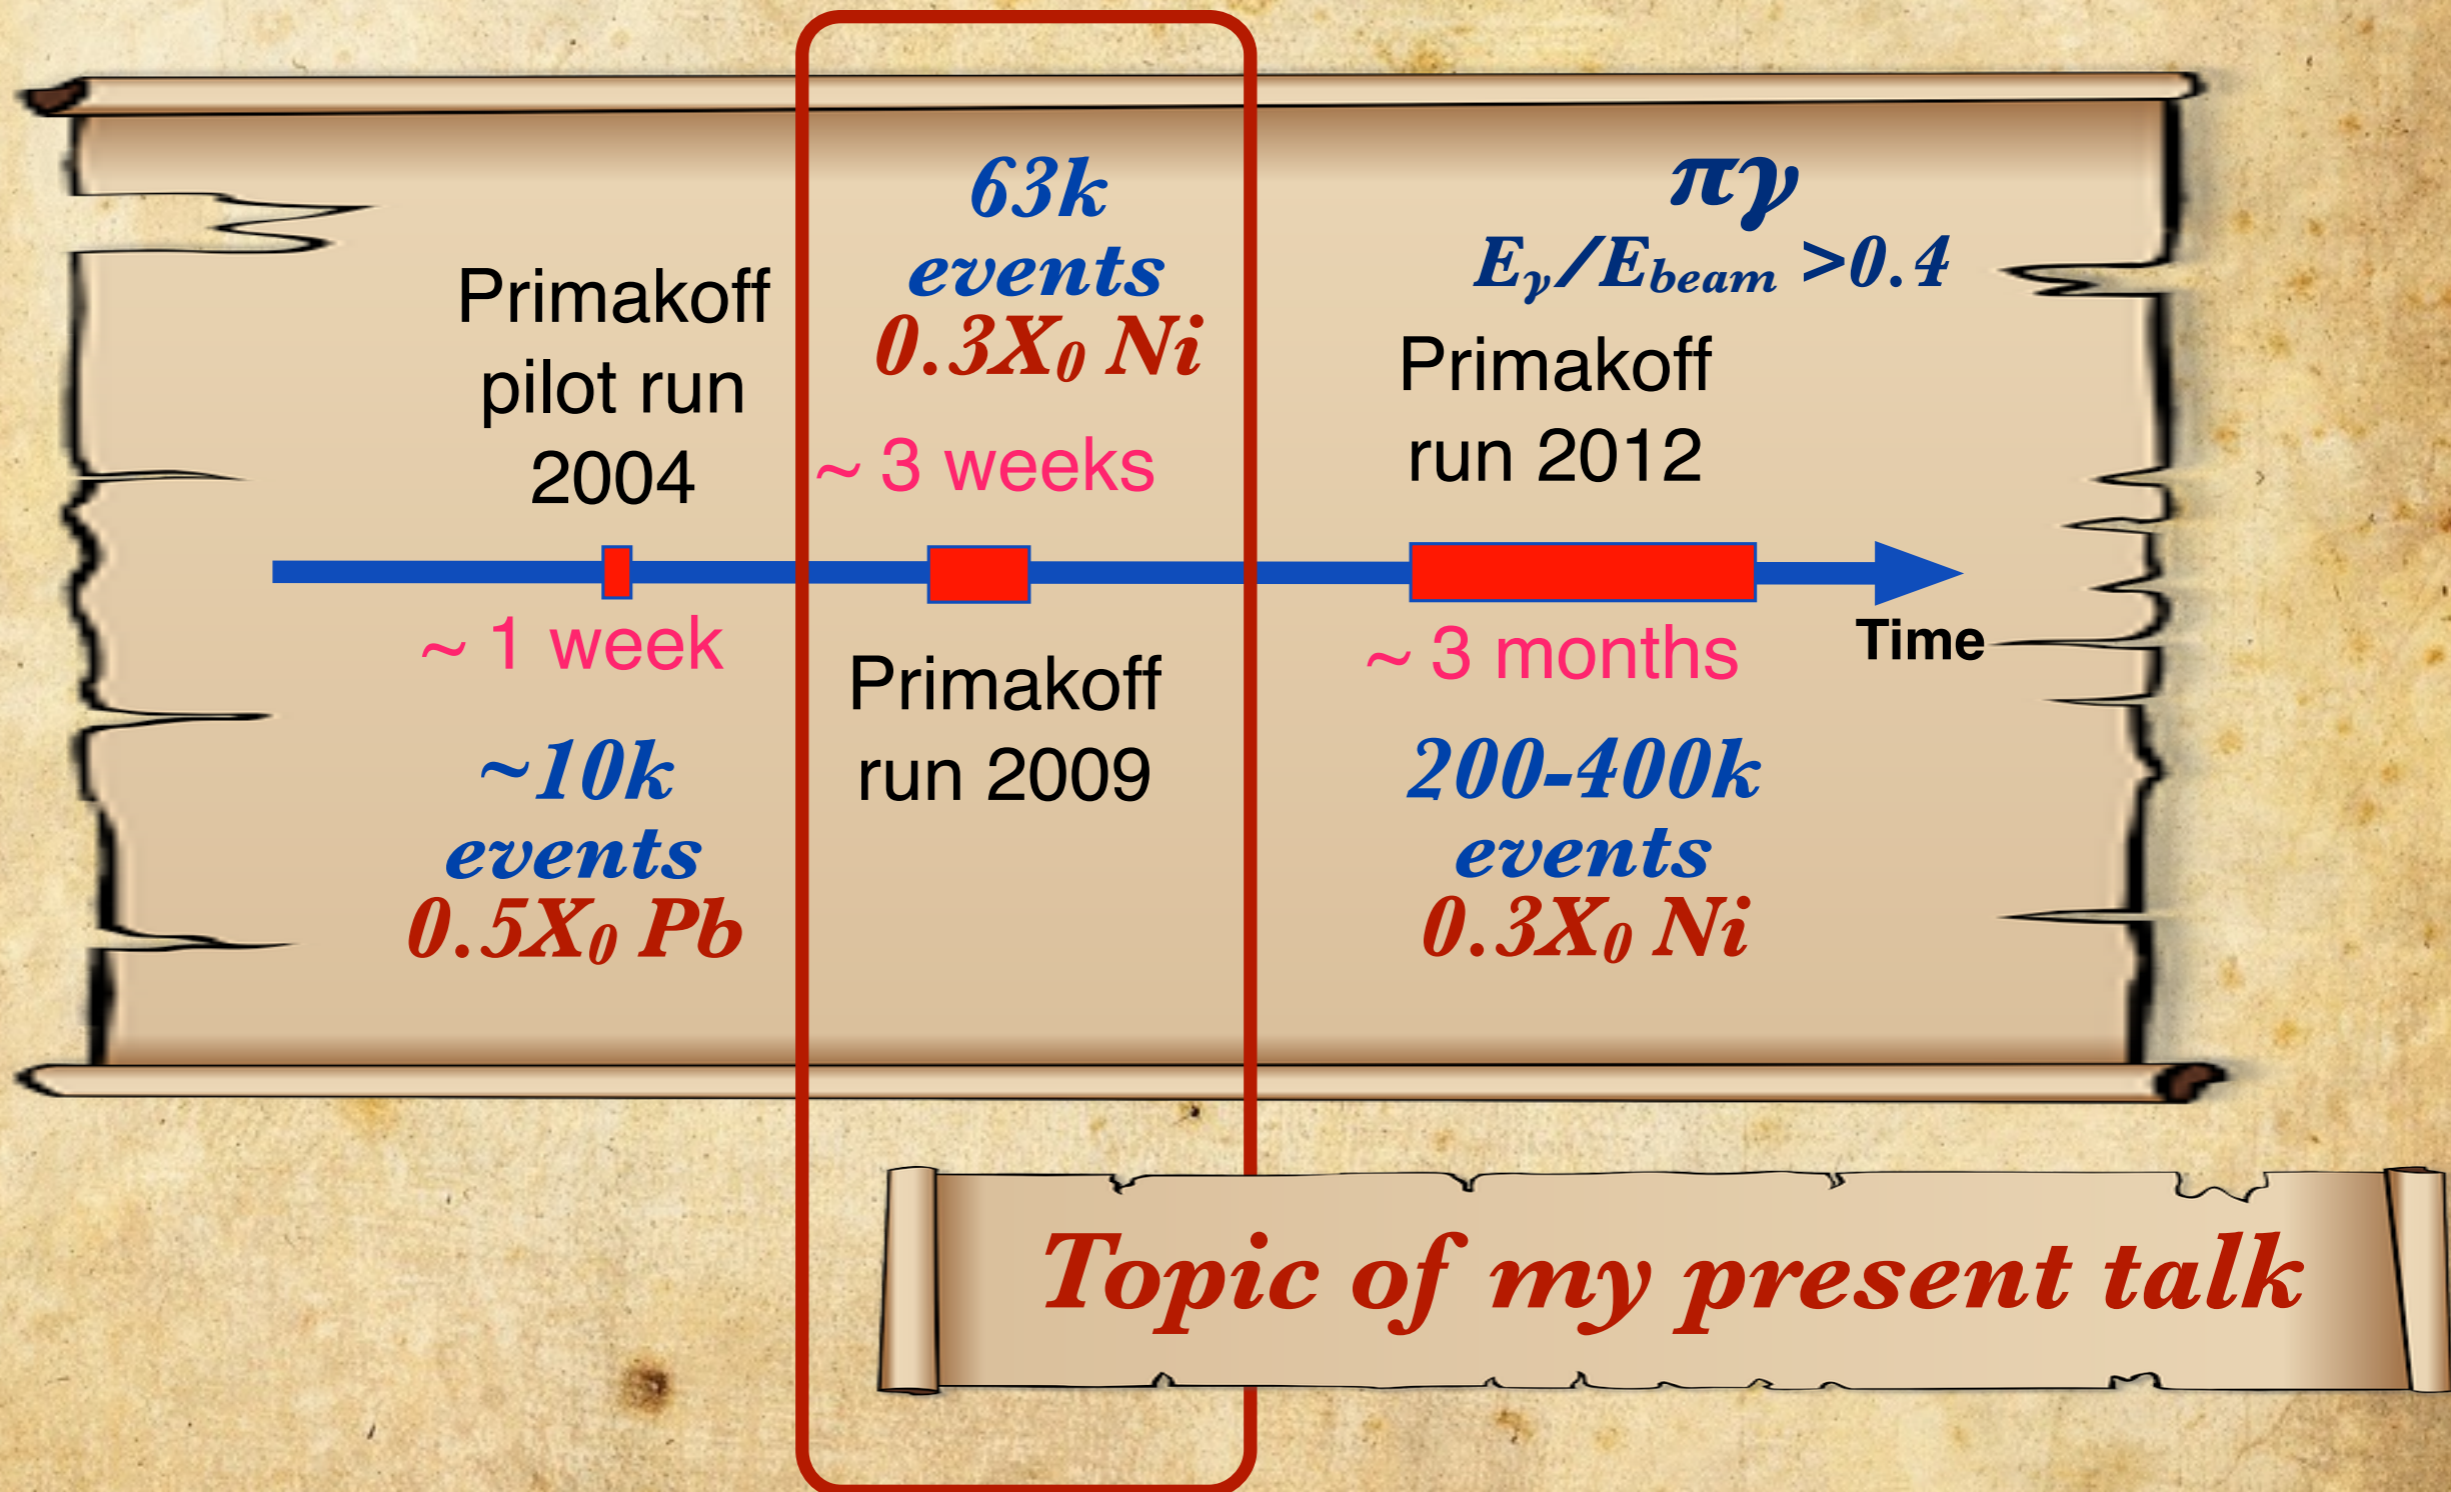

Main advantage of COMPASS

*We can use **pion** and **muon** beams of the same momentum with the same setup configuration.*

*Muon is the point-like particle and corresponding cross section for muon is known with high precision. **So, muon data can be used as reference to control our systematics.***

Primakoff runs at COMPASS

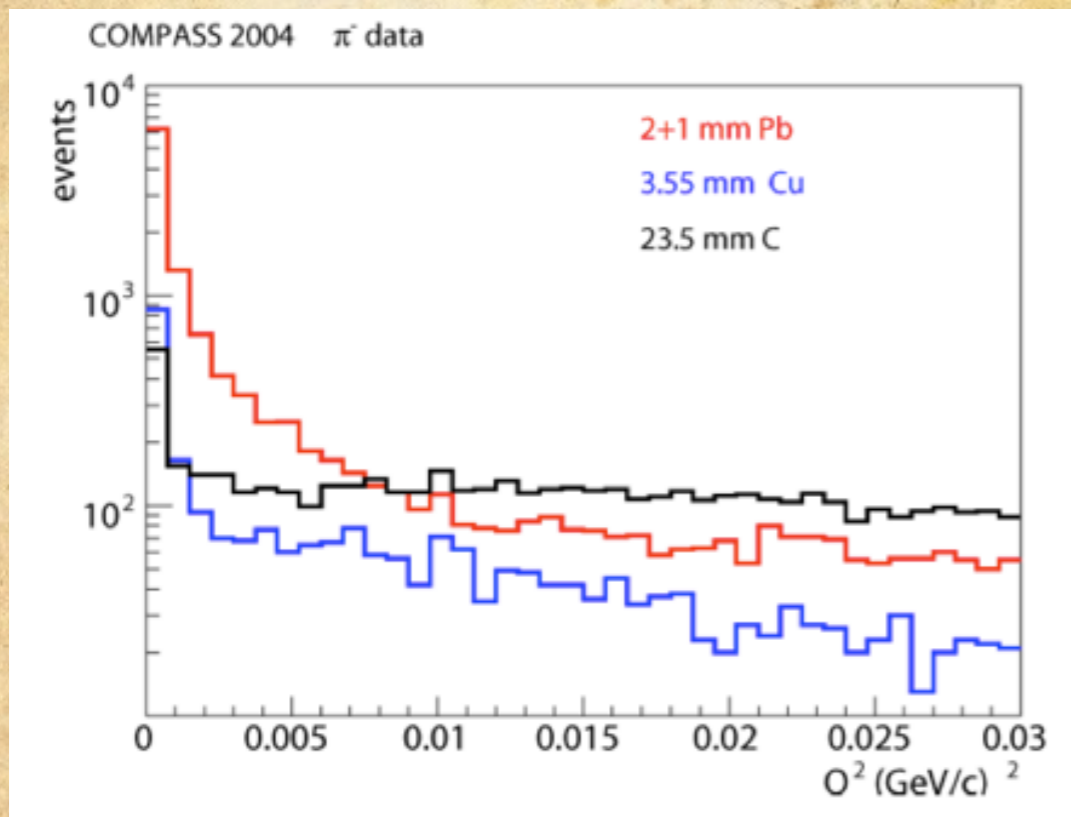

Pilot data taking in 2004

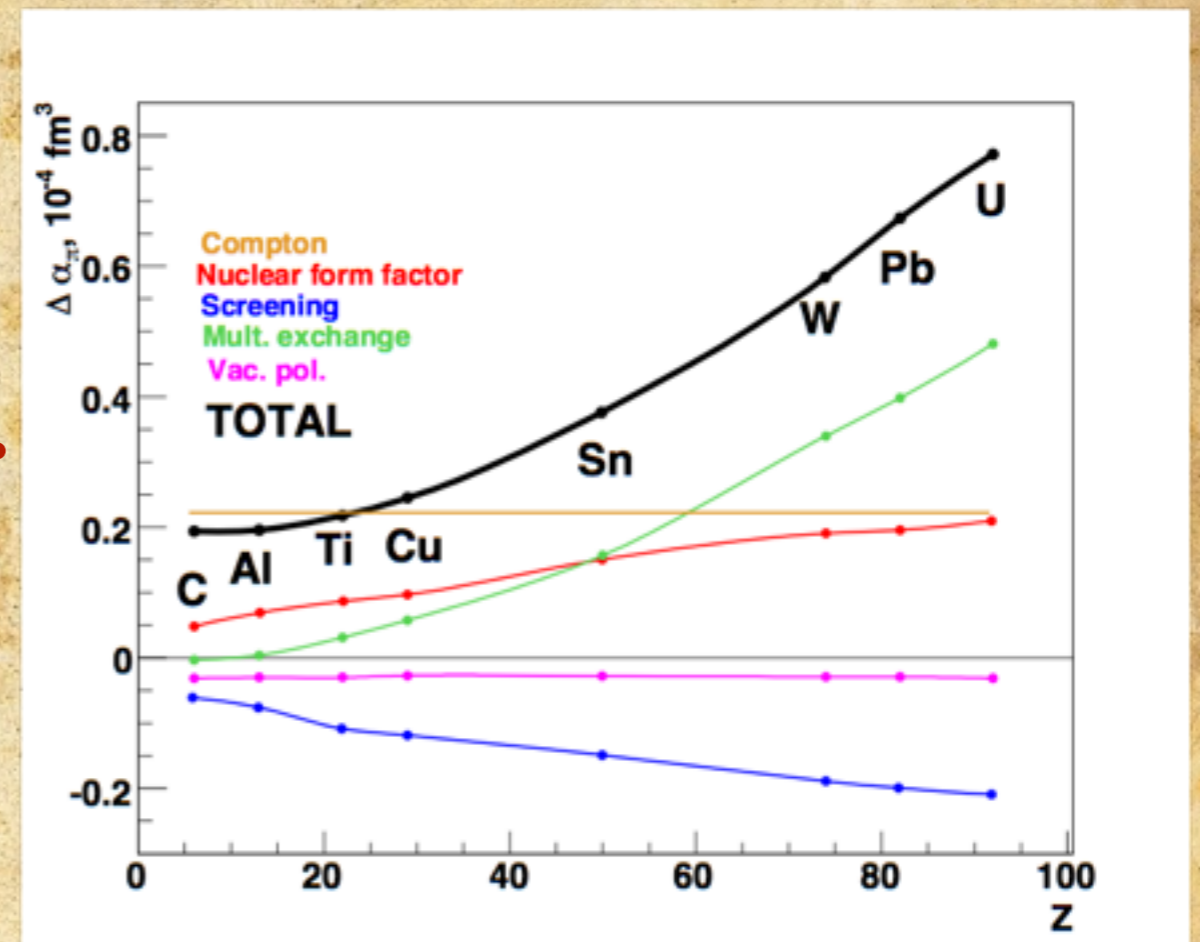

Pion radiative scattering was observed, some preliminary studies were performed

Target: $C \rightarrow Pb \rightarrow Ni$

but...

*For high Z nuclei:
we have better electromagnetic
signal to nuclear background
ratio **but...**
we much stronger depends on
calculation of numerous
corrections*

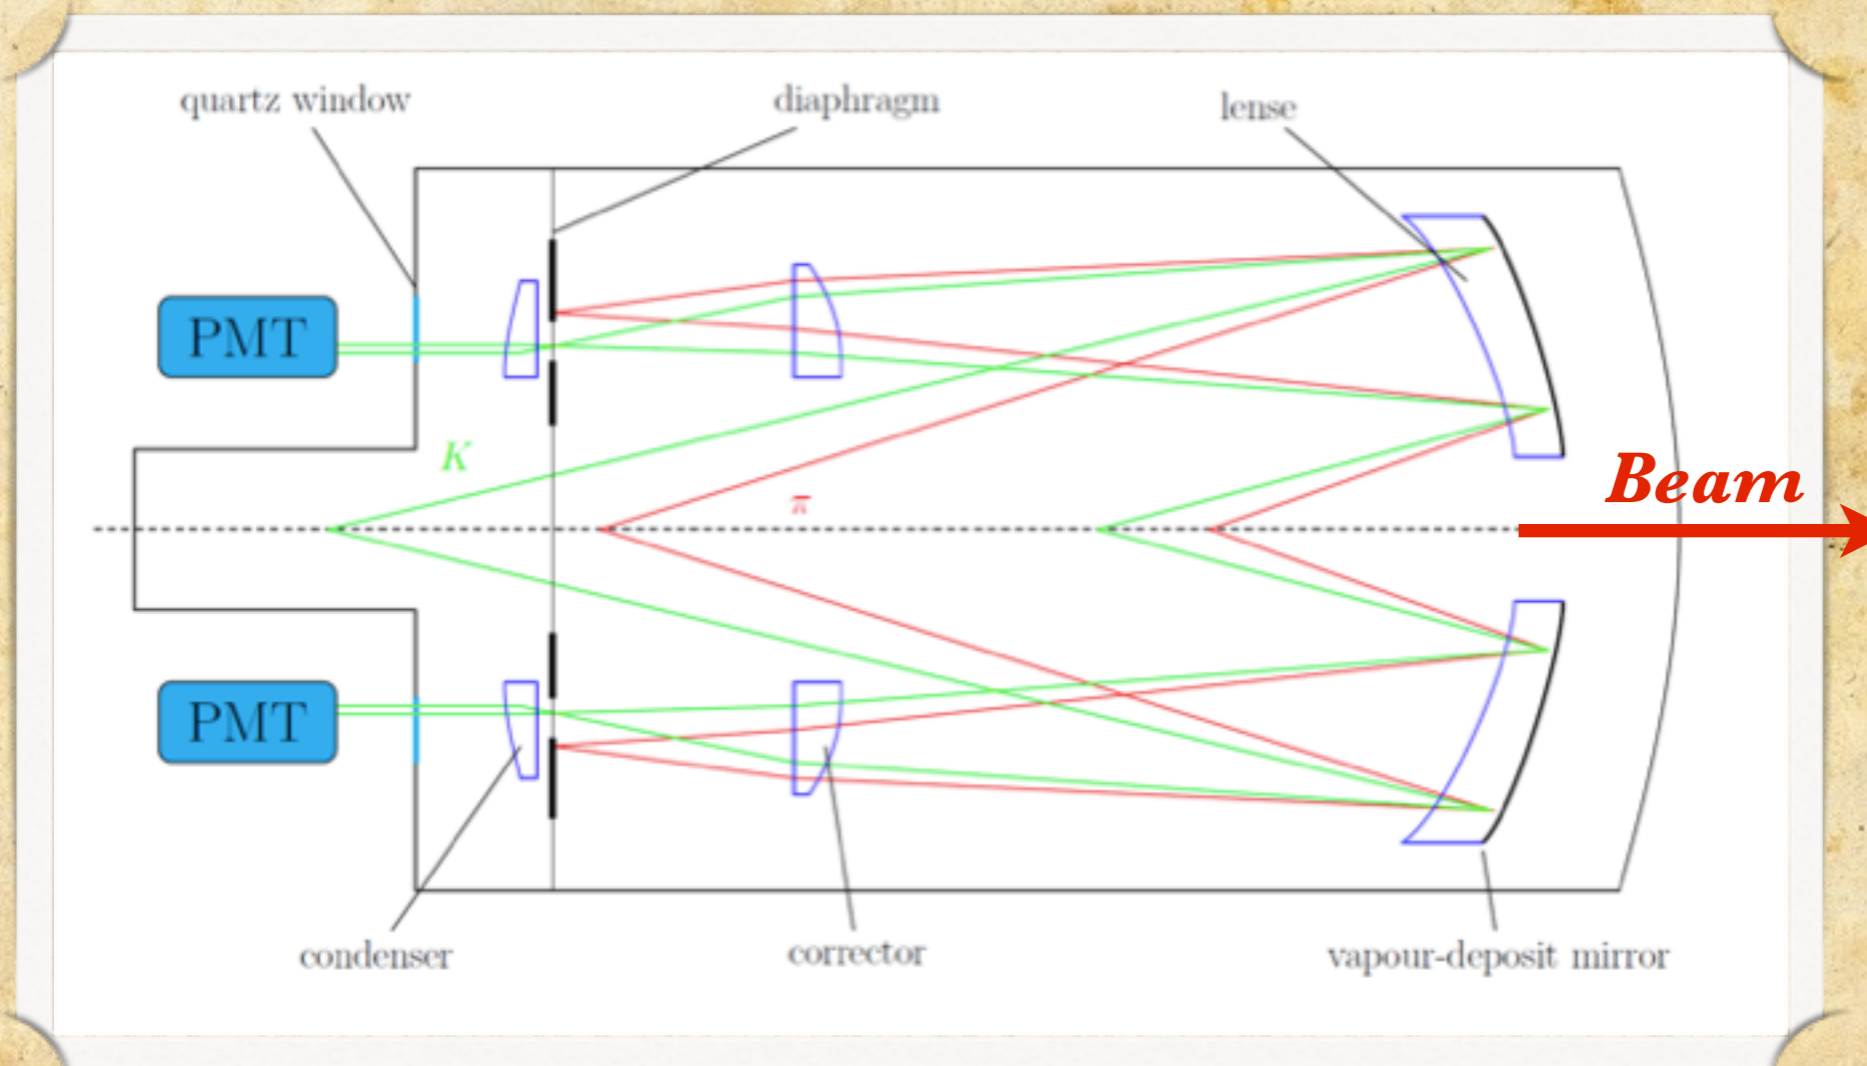

Hadron and muon beams

	Hadron	Muon
P, GeV/c	190	190
dP/P	1%	4%
σ the target, cm	0.5	0.8
Divergence, mrad	0.1	0.4
Intensity, $10^7/9.6$ s spill	4	4
Composition	π^- 96% K^- 2.4% p^- 0.8% μ^- ~1% e^- <0.01%	μ^- ~100%

CEDAR detectors

***2 differential Cherenkov counters
upstream the target***

***kaon rejection efficiency: $\sim 95\%$
for parallel beam***

Trigger

TRIGGER = (BC & ECAL2)
!SW !BK1 !BK2

Trigger name	ECAL2 threshold, GeV	Scale factor	Rate, kHz
Primakoff 1	~40	2	~20
Primakoff 2	~60	1	

Event selection

- *Primakoff1, Primakoff2 triggers*
- *1 vertex with 1 outgoing negative track*
- *No other tracks**
- *Beam track is parallel to the nominal beam axis*
- *Scattered track is not muon*
- *No activity in RPD*
- *Exactly 1 neutral cluster in ECAL2 ($E > 2$ GeV)**
- *Beam particle is pion (CEDAR)*

Kinematic cuts

p_T -cut to reject low p_T region related with multiple scattering in the material

Exclusivity cut on the level ± 15 GeV to reject events with missed particles in the final state

Kinematic cuts

$M_{\pi\gamma} < 3.5 m_\pi$ to avoid ρ -meson production and decay to $\pi\pi^0$

$Q^2 < 1.5 \times 10^{-3} (\text{GeV}/c)^2$ to reject $\pi\gamma$ state production via strong interaction

π^0 background

*single cluster
in ECAL2*

1 γ lost

*The same
selection criteria
were applied for
this channel*

*Kaon decay $K^- \rightarrow \pi^- \pi^0$
out of the target is the
reference process*

*fraction of mis-
reconstructed $\pi^- \pi^0$
events in $\pi^- \gamma$ sample*

*probability to mis-identify
 $\pi^- \pi^0$ state as $\pi^- \gamma$*

Muon data

The same selection + muon beam momentum measurement

The measured x_γ distributions

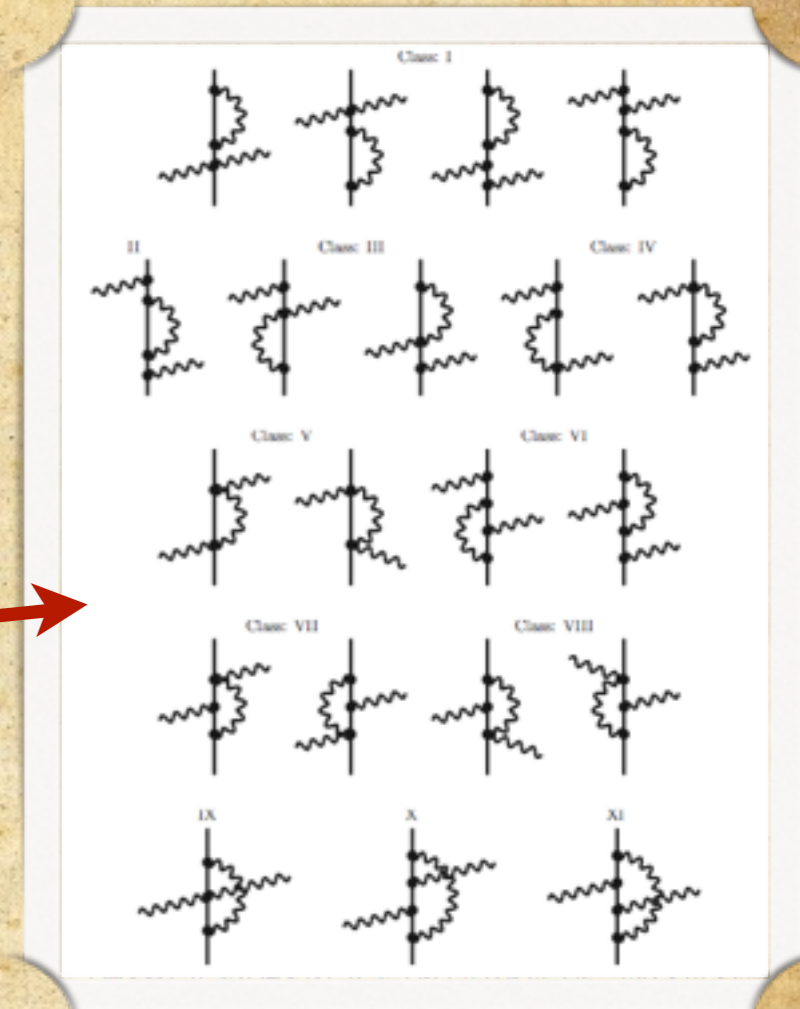

The result?

Not yet!

Corrections

- *pion rescattering*
- *radiative corrections (Compton vertex)*
- *form factor of the **Ni** nucleus*

- *High Z effects ($Z\alpha=0.2$)*
- *Nuclear charge screening by atomic electrons*

Pion polarizabilities at COMPASS

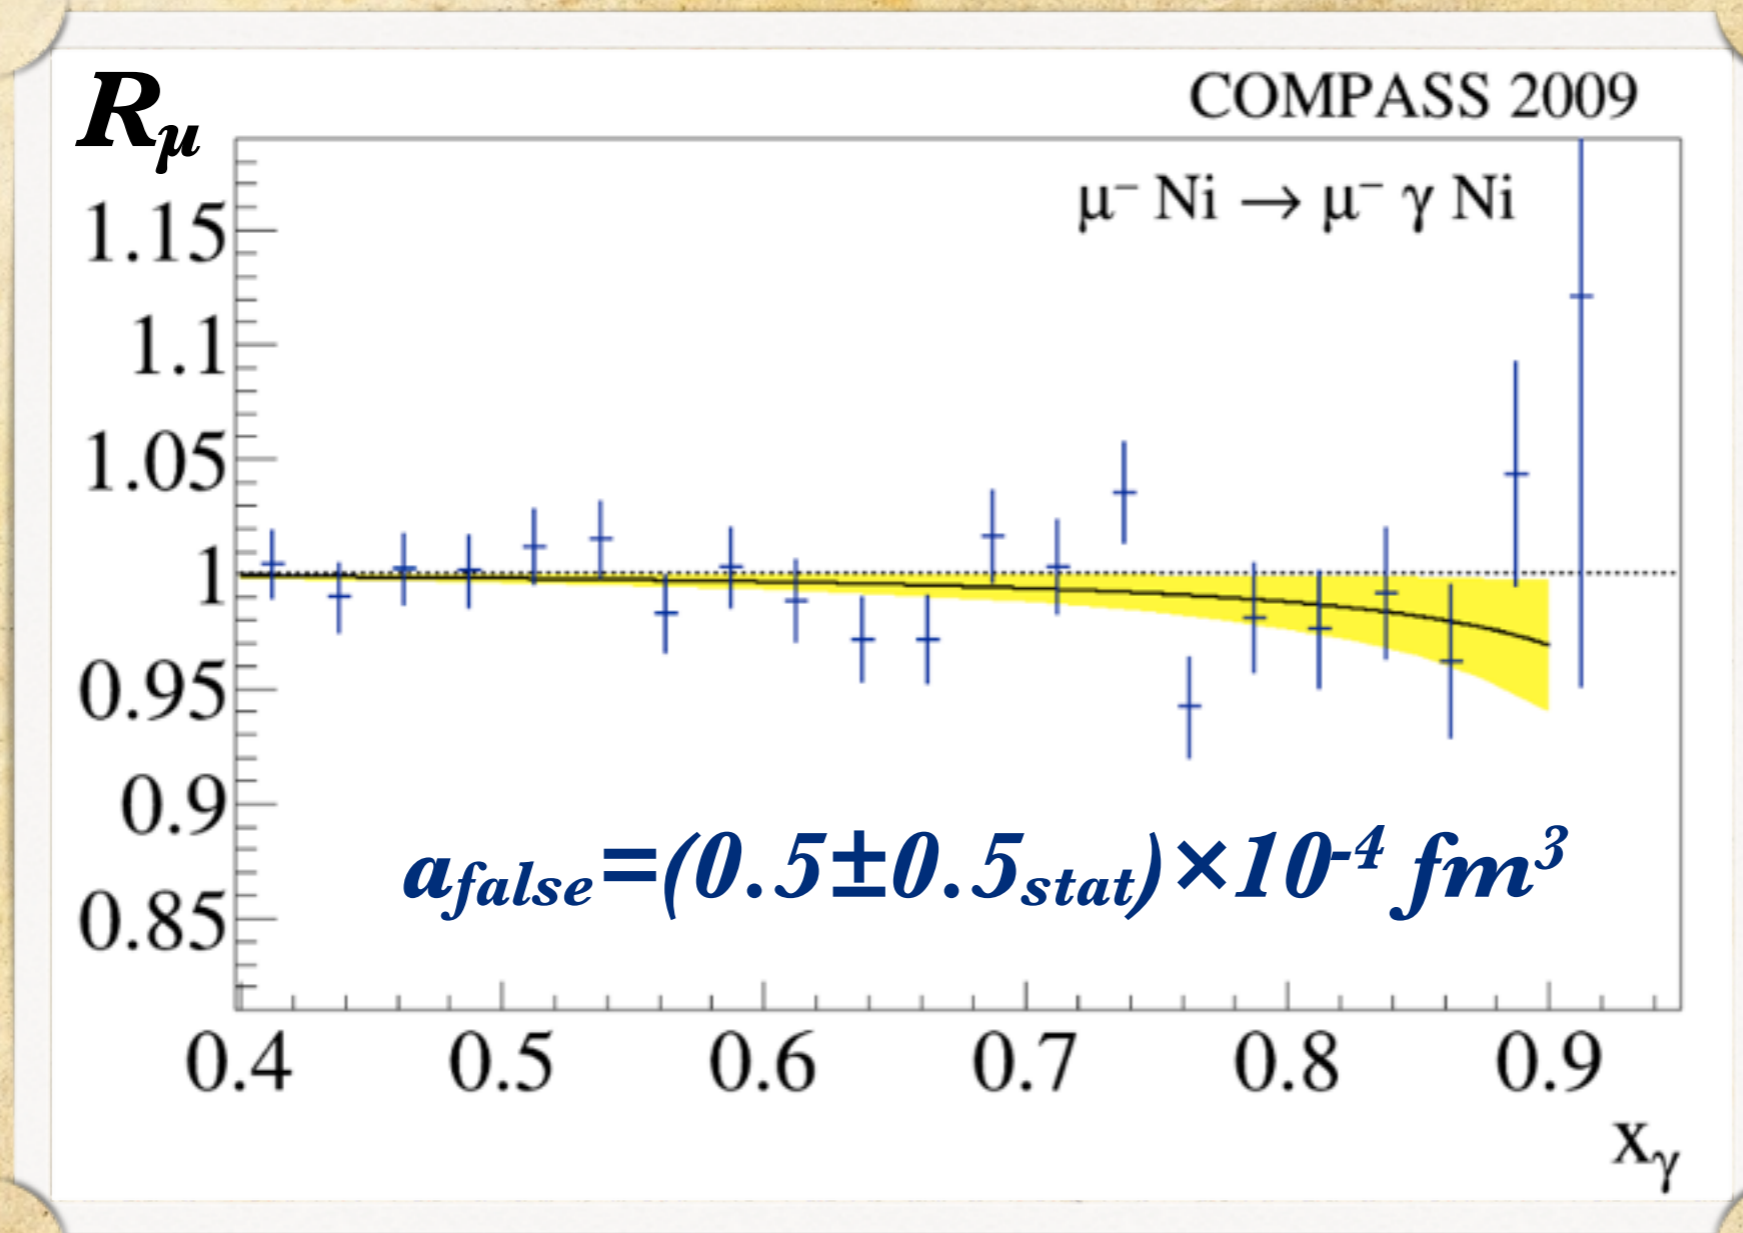

$$a_\pi = (2.0 \pm 0.6_{stat}) \times 10^{-4} \text{ fm}^3$$

Systematic effects

Source of uncertainty	Estimated magnitude [10^{-4} fm^3]
Determination of tracking detector efficiency	0.5
Treatment of radiative corrections	0.3
Subtraction of π^0 background	0.2
Strong interaction background	0.2
Pion-electron elastic scattering	0.2
Contribution of muons in the beam	0.05
Quadratic sum	0.7

$$a_{\pi} = (2.0 \pm 0.6_{stat} \pm 0.7_{syst}) \times 10^{-4} \text{ fm}^3$$

Ratio for muons

False polarizability for muon is consistent with zero within the error

The COMPASS result

2009

Source of uncertainty	Estimated magnitude [10^{-4} fm^3]
Determination of tracking detector efficiency	0.5
Treatment of radiative corrections	0.3
Subtraction of π^0 background	0.2
Strong interaction background	0.2
Pion-electron elastic scattering	0.2
Contribution of muons in the beam	0.05
Quadratic sum	0.7

Under assumption $a_\pi = -\beta_\pi$:

$$a_\pi = (2.0 \pm 0.6_{stat} \pm 0.7_{syst}) \times 10^{-4} \text{ fm}^3$$

Phys. Rev. Lett. 114 (2015) 06002

Protvino: $a_\pi = -\beta_\pi = (6.8 \pm 1.4_{stat} \pm 1.2_{syst}) \times 10^{-4} \text{ fm}^3$, $\chi\text{PT}: a_\pi \approx 2.8 \times 10^{-4} \text{ fm}^3$

Pion polarizabilities and COMPASS

2009

COMPASS preliminary result for pion polarizability is the most precise among dedicated measurements

Is a_π really a constant in our kinematic range?

Yu. Bystritskiy, A. Guskov, V. Pervushin, M. Volkov Phys. Rev. D 80, 114001 (2009)

$$t = (P_{0\pi} - P_\pi)^2$$

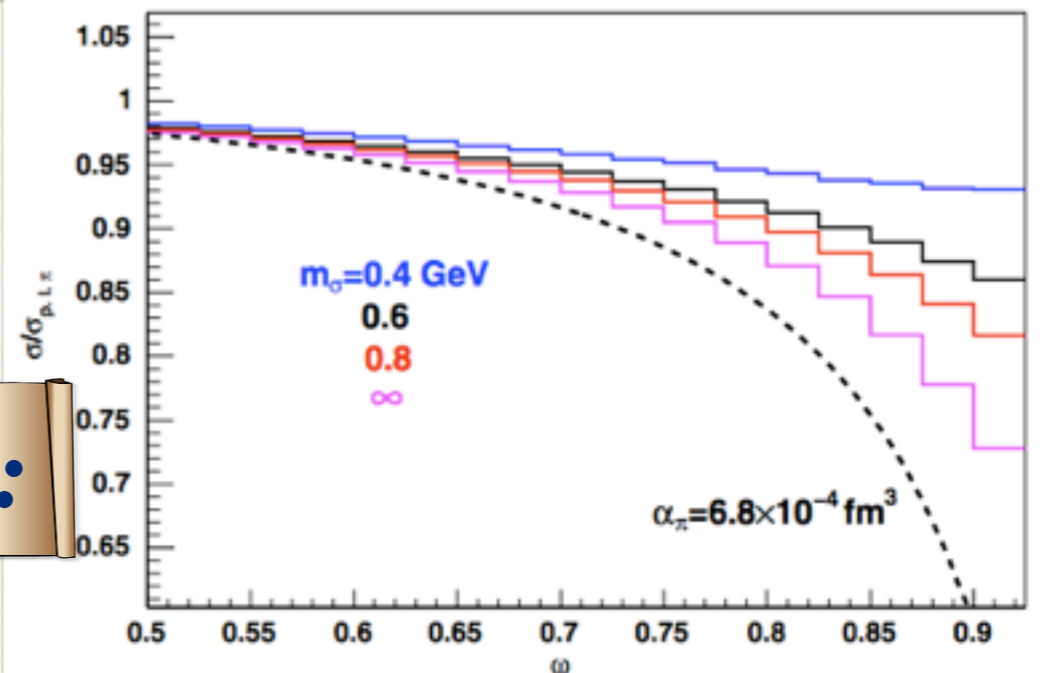

$$a_\pi(t) = a_{\pi ch} \chi(t)$$

$$a_{\pi ch} = 5.8 \times 10^{-4} \text{ fm}^3$$

m_σ - parameter of the model

NJL model:

Pion polarizabilities at COMPASS

>200k of $\pi\gamma$ events with $E_\gamma/E_{beam} > 0.4$

2012

*Primakoff data collected in
2012 provide possibility:*

- *to reduce uncertainty of a_π measurement
to $\sim 0.4 \times 10^{-4} \text{ fm}^3$*
- *to measure $a_\pi + \beta_\pi$ with accuracy $\sim 0.04 \times 10^{-4} \text{ fm}^3$ ($\chi\text{PT: } 0.16$)*
- *to study dynamics of pion polarizabilities
 $a_\pi = a_\pi(s, t, \dots)$*
- *to access quadrupole polarizabilities of
pion $a_{\pi 2}$ and $\beta_{\pi 2}$*

Kaon polarizabilities

Theoretical predictions:

χ PT prediction $O(p^4)$:

$$\alpha_K + \beta_K = 0$$

$$\alpha_K = \alpha_\pi \times \frac{m_\pi F_\pi^2}{m_K F_K^2} \approx \frac{\alpha_\pi}{5} \approx \underline{0.6 \times 10^{-4} \text{ fm}^3}$$

Quark confinement model:

$$\alpha_K + \beta_K = 1.0 \times 10^{-4} \text{ fm}^3$$

$$\alpha_K = \underline{2.3 \times 10^{-4} \text{ fm}^3}$$

Experimental results:

$$\alpha_K = (-4 \pm 11) \times 10^{-4} \text{ fm}^3$$

- from kaonic atoms spectra

At COMPASS:

- $\sim 2.4\%$ of kaons in hadron beam
- CEDARs for beam kaons identification

Polarization effects
 $\sim m^3$

$$\sigma_{Prim} \sim \frac{1}{m^2}$$

1 $K\gamma$ event
per 500 $\pi\gamma$

a_π at JLab (proposal)

http://www.jlab.org/exp_prog/proposals/13/PR12-13-008.pdf

Existing detector *GlueX* at Hall-D

- Polarized photons of ~ 6 GeV
- 10^7 tagged photons per second
- 0.6 mm ^{106}Sn target
- 20 days of data taking
- Accuracy $0.3 \times 10^{-4} \text{ fm}^3$

Main physical backgrounds:

- pion pair production in strong interaction
- coherent ρ^0 production
- production of lepton pairs

Approved by JLab PAC

Summary

● *The COMPASS experiment performed the most precise measurement of pion polarizability α_π under assumption $\alpha_\pi + \beta_\pi = 0$ basing on the data of 2009 year.*

● *The result is:*

$$\alpha_\pi = (2.0 \pm 0.6_{\text{stat}} \pm 0.7_{\text{syst}}) \times 10^{-4} \text{ fm}^3$$

● *This result is published in Physical Review Letters: [PRL 114 \(2015\) 06002](#)*

● *Contribution of **JINR** group to this result is determinative at each stage from planning to data taking and analysis*

● *COMPASS Primakoff data of 2012 still are under analysis and new results for pion (and kaon) polarizabilities are expected*
